# Lithium batteries can store electricity at intervals

## Overview

---

Lithium can store electricity largely due to its high electrochemical potential, lightweight nature, and excellent cycle life. What is a lithium ion battery?

Lithium-ion batteries (LIBs) are electrochemical energy converters that play an important part in everyday life, powering computers, tablets, cell phones, electric cars, electric bicycles, and numerous other devices. They can also be used to store intermittently produced renewable energy.

Which principle applies to a lithium-ion battery?

The same principle as in a Daniell cell, where the reactants are higher in energy than the products, 18 applies to a lithium-ion battery; the low molar Gibbs free energy of lithium in the positive electrode means that lithium is more strongly bonded there and thus lower in energy than in the anode.

How do lithium-ion batteries work?

First published on 10th September 2024 A good explanation of lithium-ion batteries (LIBs) needs to convincingly account for the spontaneous, energy-releasing movement of lithium ions and electrons out of the negative and into the positive electrode, the defining characteristic of working LIBs.

What happens when lithium ion is released from a battery?

As the battery discharges, graphite with loosely bound intercalated lithium ( $\text{Li}_x\text{C}_6(\text{s})$ ) undergoes an oxidation half-reaction, resulting in the release of a lithium ion and an electron.

Why does a lithium ion battery have a different electric potential?

In a good lithium-ion battery, the difference in electron electrochemical potential between the electrodes is mostly due to the electric potential difference  $\Delta \phi$  resulting from (chemically insignificant amounts of) excess charge on the electrodes that are maintained by the chemical reaction.

Why do electrons move in a lithium-ion battery?

(This is the electrical-potential term –  $F \Delta \phi$  in the difference between the electrochemical potentials  $e^-$  of electrons in the electrode-attached copper leads.) Various publications<sup>14,16,42</sup> have attributed the movement of electrons in a lithium-ion battery to the difference in the chemical potential of the electron in the electrodes.
